MAGNITUD DE UN TEMBLOR

(ESCALA RICHTER)

La ecuación que utiliza la Red Sismológica Nacional para determinar la magnitud (MD) de un sismo, se estimó efectuando una comparación directa con la magnitud local (ML) de Richter, para un sismógrafo Wood Anderson calibrado para Ml que funcionó en la Universidad de Costa Rica de 1976 a 1984.

$$MD = -1,21 + 2,38 \log_{10} D + 0,0012 DH.$$

MD = Magnitud local en base a la duración de la señal.

D = Es la duración **Coda** del registro sísmico en segundos en la estación **SJS**.

= Distancia hipocentral (desde la estación San José SJS).

$$K = 8,2$$

DH = (S-P) * K donde (S-P) es la diferencia de los tiempos S y P obtenidos de las velocidades de las ondas sísmicas.

K = Constante.

Así un sismo que se registre en la estación San José (SJS), con una duración de 100 segundos y a 76 km de distancia desde el hipocentro, tendrá una magnitud local o MD = 3,6 (Escala Richter).

Elaborada por: Geól. Wilfredo Rojas Q, 1992

PARTE A PART A

Esta parte del boletín contiene un listado los parámetros focales y un mapa de los sismos locales de magnitud $\geq 3,5$ registrados por las estaciones de la Red Sismológica Nacional (RSN: ICE-UCR) y además un mapa de epicentros con todos los sismos localizados por esta red durante cada mes.

This part of the bulletin contains a list the focal parameters and a map of all the local earthquakes with magnitude ≥ 3.5 registered by the Red Sismológica Nacional (RSN: ICE-UCR) stations and also contains an epicentral map with all the localized earthquakes by this network during each month.
